

## Likely existence of bound states and the Efimov effect in the triple- $J/\psi$ system

The ground-breaking discovery of the first fully charmed tetraquark state  $X(6900)$  in the  $J/\psi J/\psi$  invariant mass distribution by the LHCb collaboration has inspired intensive theoretical studies. Various interpretations, such as molecular states, compact tetraquark states, and coupled-channel effects, have been proposed for these states. Of particular interest is the ongoing search for the triple- $J/\psi$  state—a fully-charmed hexaquark state. To deepen our understanding of the triple- $J/\psi$  state and to guide future experimental searches, we study the triple- $J/\psi$  system in this work employing the Gaussian expansion method and with the  $J/\psi J/\psi$  potential parameterized to yield a shallow bound state, as suggested in several theoretical works. Our results support a triple- $J/\psi$  bound state, even in cases where the attractive interaction between the two  $J/\psi$  mesons is very weak. Moreover, our analysis implies the Efimov effect in the triple- $J/\psi$  system. In addition, we extend our investigation to the triple- $\Upsilon(1S)$  system and obtain results similar to those for the triple- $J/\psi$  system.

### Field of Research

Hadrons

### Experiment/Theory

Theory
